If you gradually increase the amount of damping in a system, the period and frequency begin to be affected, because damping opposes and hence slows the back and forth motion. (The net force is smaller in both directions.) If there is very large damping, the system does not even oscillate—it slowly moves toward equilibrium.

The paddle ball on its rubber band moves in response to the finger supporting it. If the finger moves with the natural frequency of the ball on the rubber band, then a resonance is achieved, and the amplitude of the ball's oscillations increases dramatically. At higher and lower driving frequencies, energy is transferred to the ball less efficiently, and it responds with lower-amplitude ...

We can see from this graph that when the neuron's output is close to \$1\$, the curve gets very flat, and so $\sigma'(z)$ gets very small. Equations (55) and (56) then tell us that $\frac{\partial C}{\partial \theta}$

w and $\partial C / \partial b$ get very small. This is the origin of the learning slowdown.

Statics is the branch of mechanics that is concerned with the analysis of loads (force and torque, or "moment") acting on physical systems that do not experience an acceleration ($a=0$), but rather, are in static equilibrium with their environment. When in static equilibrium, the acceleration of the system is zero and the system is either at rest, or its center of mass moves at constant velocity.

Professor PZ Myers demonstrates one more time how ID advocates misrepresent scientific data, trying to utilize them for their own goals. The case in point is a high-quality scientific article analyzing the process of the increase in size of life forms over the millennia; the authors of that paper found links between the organism's size increase and the evolution of the earth atmosphere's ...
