A list. Objects, as generic blobs of values, can be used to build all sorts of data structures. A common data structure is the list (not to be confused with array). A list is a nested set of objects, with the first object holding a reference to the second, the second to the third, and so on.

5.3. Tuples and Sequences¶. We saw that lists and strings have many common properties, such as indexing and slicing operations. They are two examples of sequence data types (see Sequence Types — list, tuple, range). Since Python is an evolving language, other sequence data types may be added.

9.2.3 Basic Linked List Processing. It is very common to want to process all the items in a linked list in some way. The common pattern is to start at the head of the list, then move from each node to the next by following the pointer in the node, stopping when the null that marks the end of the list is reached. If head is a variable of type Node that points to the first node in the list, then ...

Most modern business application development projects use object technology such as Java or C# to build the application software and relational databases to store the data. This isn't to say that you don't have other options, there are many applications built with procedural languages such as COBOL and many systems will use object databases or XML databases to store data.

Visual Basic for Applications (VBA) facilitates many useful data structures – its not just VBA Arrays you can use. COM libraries provide additional data structures such as the VBA Dictionary, ArrayList, Queue, Stack or SortedList. But before we jump into explaining how these more complex data structures work and how to use them, let's start with the basics – VBA array.
